Definitions

- If A, B ≤ G, A permutes with B when AB = BA, that is, AB is a subgroup of G.
- A is permutable or quasinormal in G if H permutes with all subgroups of G (Ore, 1939).

Lemma

Let \mathfrak{X} be a family of subgroups of a group G. If a subgroup A of G permutes with all subgroups $X \in \mathfrak{X}$, then it also permutes with their join $< \mathfrak{X} >$.

Therefore a subgroup *A* of a periodic group *G* is permutable in *G* if and only if *A* permutes with every *p*-subgroup of *G* for all $p \in \pi(G)$.

Let π a set of primes. A subgroup *A* of a periodic group *G* is called:

Definition

- π -permutable in *G* if *A* permutes with every *q*-subgroup of *G* for all $q \in \pi$.
- π -S-permutable or π -S-quasinormal in *G* if *A* permutes with every Sylow *q*-subgroup of *G* for all $q \in \pi$ (Kegel 1962).

If π is the set of all primes, then the π -permutable subgroups are just the permutable subgroups; the π -S-permutable subgroups are called S-permutable. In the case when $\pi = \pi(G) \setminus \pi(A)$, then *A* is called semipermutable (respectively, S-semipermutable) in *G* (Chen 1987).

Theorem (Kegel (1962), Deskins (1963))

If A is an S-permutable subgroup of a finite group G, then A/A_G is contained in the Fitting subgroup of G/A_G . In particular, A is subnormal in G.

In particular, every permutable subgroup is subnormal (Ore, 1939).

Theorem (Maier and Schmid, 1973)

If A is a permutable subgroup of a finite group G, then A/A_G is contained in the hypercentre of G/A_G .

- There are examples of permutable subgroups *A* of finite groups *G* such that A/A_G is not abelian (Thompson, 1967).
- There is no bound for the nilpotency class of a core-free permutable subgroup (Bradway, Gross and Scott, 1971).
- There is no bound for the derived length of a core-free permutable subgroup (Stonehewer, 1974).

Definition (Carocca and Maier 1998)

A subgroup A of a group G is called hypercentrally embedded in G if A/A_G is contained in the hypercentre of G/A_G .

Every S-permutable subgroup of a finite group is hypercentrally embedded in *G*, but the converse is not true in general.

S-permutable subgroups of a finite group G form a sublattice of the subgroup lattice of G.

According to a result of Dixon, Kegel's lattice result also holds for radical locally finite groups with $\min-p$ for all p. We do not know whether

- 3-permutable subgroups is a sublattice of the subgroup lattice of a finite *G*, even in finite soluble groups.
- Kegel's result holds for locally finite groups.

Permutability

Theorem (B-B, Beidleman, Esteban-Romero and Ragland, 2014)

Let G be a group with nilpotent residual L, $\pi = \pi(L)$. Let θ_1 (respectively θ_2) denote the set of all primes p in $\theta = \pi'$ such that G has a non-cyclic (respectively cyclic) Sylow p-subgroup. Then every maximal subgroup of G is S-semipermutable if and only if G satisfies the following:

- 1. G is a T_0 -group.
- 2. L is a nilpotent Hall subgroup of G.
- 3. If $p \in \pi$ and P is a Sylow p-subgroup of G, then a maximal subgroup of P is normal in G.

Theorem (B-B, Li, Su and Xie, 2014)

Let p be a prime and let A be a p'-subgroup of a finite group G. Assume that A permutes with every p-subgroup of G. Then every chief factor of A^G whose order is divisible by p is simple and isomorphic to one of the following groups:

3
$$PSL(n,q)$$
, $n > 2$ prime, $p = \frac{q^n - 1}{q - 1}$, or $PSL(2, 11)$, $p = 11$,

•
$$M_{23}$$
