## Low-Multiplicative Non-Linear Invertible Functions

A low-multiplicative non-linear function is a function that requires a small number of non-linear operations (multiplications).

These functions over prime fields  $\mathbb{F}_p$  for  $p \ge 3$  prime are very relevant for symmetric encryption schemes like

- Multi Party Computation (MPC);
- Zero-Knowledge proofs (ZK);
- Fully Homomorphic Encryption (FHE).

These two equations are:

$$\alpha_{0,2;1} \cdot d_2 \cdot s_2 + \frac{\alpha_{1,1;1}}{2} \cdot d_2 \cdot s_1 + \alpha_{0,1;1} \cdot d_2 = 0,$$

$$\alpha_{2,0;0} \cdot d_2 \cdot s_2 + \frac{\alpha_{1,1;0}}{2} \cdot d_2 \cdot s_3 + \alpha_{1,0;0} \cdot d_2 = 0,$$

where  $d_i = x_i - y_i$  and  $s_i = x_i + y_i$ .

#### Lemma

Consider the case with  $F_0$ ,  $F_1$  two quadratic functions such that  $\alpha_{1,1;0} \neq 0$ ,  $\alpha_{1,1;1} \neq 0$  and  $n \geq 4$  even number. Then  $\mathcal{S}_{F_0,F_1}$  over  $\mathbb{F}_p^n$  is not invertible.

Proof: Inputs  $(x_0, x_1, x_2, x_3, \dots, x_{n-1})$  and  $(y_0, y_1, y_2, y_3, \dots, y_{n-1}) = (x_0, x_1, y_2, x_3, \dots, x_{n-1}), y_2 \neq x_2.$ 

 $\implies \mathcal{S}_{F_0,F_1}(x_0, x_1, x_2, x_3, \dots, x_{n-1}) = \mathcal{S}_{F_0,F_1}(x_0, x_1, y_2, x_3, \dots, x_{n-1}) \text{ reduces to}$ the two equations  $F_1(x_1, x_2) = F_1(x_1, y_2)$  and  $F_0(x_2, x_3) = F_0(y_2, x_3)$ .

These two equations are:

$$\alpha_{0,2;1} \cdot \boldsymbol{d}_2 \cdot \boldsymbol{s}_2 + \frac{\alpha_{1,1;1}}{2} \cdot \boldsymbol{d}_2 \cdot \boldsymbol{s}_1 + \alpha_{0,1;1} \cdot \boldsymbol{d}_2 = \boldsymbol{0},$$

$$\alpha_{2,0;0} \cdot d_2 \cdot s_2 + \frac{\alpha_{1,1;0}}{2} \cdot d_2 \cdot s_3 + \alpha_{1,0;0} \cdot d_2 = 0,$$

where  $d_i = x_i - y_i$  and  $s_i = x_i + y_i$ .

Invertible Quadratic Functions -Multiple Maps

About the Proof

#### Since $d_2 \neq 0$ , the system can be written as

$$\begin{pmatrix} \frac{\alpha_{1,1;1}}{2} & \mathbf{0} \\ \mathbf{0} & \frac{\alpha_{1,1;0}}{2} \end{pmatrix} \times \begin{pmatrix} \mathbf{s}_1 \\ \mathbf{s}_3 \end{pmatrix} = - \begin{pmatrix} \alpha_{0,2;1} \cdot \mathbf{s}_2 + \alpha_{0,1;1} \\ \alpha_{2,0;0} \cdot \mathbf{s}_2 + \alpha_{1,0;0} \end{pmatrix}$$

## Since $d_2 \neq 0$ , the system can be written as

$$\begin{pmatrix} \frac{\alpha_{1,1;1}}{2} & \mathbf{0} \\ \mathbf{0} & \frac{\alpha_{1,1;0}}{2} \end{pmatrix} \times \begin{pmatrix} \mathbf{s}_1 \\ \mathbf{s}_3 \end{pmatrix} = - \begin{pmatrix} \alpha_{0,2;1} \cdot \mathbf{s}_2 + \alpha_{0,1;1} \\ \alpha_{2,0;0} \cdot \mathbf{s}_2 + \alpha_{1,0;0} \end{pmatrix}$$

We can see that the determinant is never zero in this case, so the system is compatible. But this means that there is a collision.

## Considerations

- Due to the definition of the ASI-lifting, we needed to prove separately the case with *n* even and *n* odd, because if *n* is odd, the numbers of the repetitions of F<sub>0</sub> and F<sub>1</sub> are different;
- CAREFUL: When *n* is odd, we considered both the cases with  $F_0$  linear and  $F_1$  quadratic and vice versa, because these cases are NOT equivalent
- We have basically an impossibility result, with few exceptions: if we relax the conditions over the two functions to a linear one and a quadratic one, we get
  - If for  $n \ge 4$  the already known Type-II Feistel schemes;
  - for n = 3 and if  $F_0$  is the linear function, one more type of invertible ASI-lifting.

## Possible Generalizations

There are two main ways in which this work can be generalized:

- by considering local maps  $F_0, F_1, \ldots, F_{h-1} : \mathbb{F}_p^m \to \mathbb{F}_p$  defined over a larger input domain by taking  $m \ge 3$ ;
- In the current definition, the function F takes in input consecutive elements  $x_i, x_{i+1}, \ldots, x_{i+m-1}$ . A possible way to generalize such definition consists of allowing for non-consecutive inputs.
